

Bacteriological Analysis @ ICWaR

Our laboratory provides comprehensive bacteriological analysis to assess microbial contamination in water, ensuring its safety for consumption, sanitation, and environmental health. This analysis focuses on detecting coliform bacteria and *Escherichia coli* (E. Coli), key indicators of waterborne pathogens and potential faecal contamination. Monitoring these microorganisms is essential for public health protection and regulatory compliance. To ensure rapid, accurate, and reliable detection, we employ the ReadyCult technique, a one-step, ready-to-use method designed for efficient microbiological assessment. This advanced technique utilises a pre-prepared snap-pack medium that, when mixed with a water sample and incubated, produces a distinct colour change to indicate the presence of total coliforms and E. coli. The ReadyCult method offers several advantages, including:

- Rapid detection – Delivers results within 24 hours, enabling timely decision-making.
- High sensitivity and specificity – Ensure accurate identification of microbial contaminants.
- Convenient and standardised – Minimizes the risk of cross-contamination and enhances reproducibility.

Our bacteriological testing services are ideal for drinking water facilities, wastewater treatment plants, environmental monitoring programs, and industrial applications, helping ensure compliance with national and international water quality standards.
